Convergence and adiabatic elimination for a
driven dissipative quantum harmonic oscillator*

March 24, 2015

Abstract

We prove that a harmonic oscillator driven by Lindblad dynamics where
the typical drive and loss channels are two-photon processes instead of single-
photon ones, converges to a protected subspace spanned by two coherent
states of opposite amplitude. We then characterize the slow dynamics in-
duced by a perturbative single-photon loss on this protected subspace, by
performing adiabatic elimination in the Lindbladian dynamics.

1 Introduction

The harmonic oscillator is a standard quantum system. It features coherent states,
equivalent of classical harmonic oscillator amplitudes, whose coherent superposi-
tions also called “cat states” feature genuinely quantum properties with no classical
equivalent. In a recent paper [8], our collaborators take advantage of this fact to
propose an implementation of logical quantum bits as “cat states”, with potential
to realize universal quantum computation using standard technological elements
as quantum gates. Their key contribution, besides the insight that the cat states
are inherently insensitive to part of the typical perturbations, is the design of an
“engineered reservoir” that stabilizes a subspace of such states in open loop.

The contribution of the present paper is to precisely establish, from the Lind-
blad master equation (2), the stabilization properties of this scheme both,

• in ideal situations with $\epsilon = 0$, by proving in theorem 1 global convergence
of the infinite-dimensional nominal model towards the target “protected sub-
space”,

in presence of a small but dominant decoherence source with \( \epsilon > 0 \), by establishing the approximate slow dynamics as a reduced Lindblad master equation (15).

The first goal builds on a typical Lyapunov-LaSalle strategy, with additional care needed due to the infinite dimension. For the second goal, we resort to a separation of the quantum dynamics into fast and slow components. We then apply an adiabatic elimination of the fast system to deduce a good approximation of the dynamics on a slow manifold, with the state remaining \( \epsilon \)-close to the protected subspace. Studying such perturbations is standard for quantum Hamiltonian systems, where regular perturbation theory can be routinely applied [11], but the Lindbladian case with singular perturbations has attracted much less attention. In [9] and similarly [10] singular perturbations up to second order are applied to a system with \( N \) ground states and eliminating relaxing excited states. In [1, 13] specific atom optics dynamics and an ancilla-mediated feedback are investigated with the standard approach of [2]. In [6] the so-called Schrieffer-Wolff formalism is generalized to Lindbladian dynamics; its basic form requires inversion of the nominal dynamics operator, which is not too practical and which we circumvent here for the derivation of the reduced slow master equation (15).

The paper is organized as follows. Section II describes the mathematical model of the dynamics to be studied. Section III provides the global convergence proof for an idealized model, and Section IV analyzes precisely how this allows to counter the dominant external perturbation, which is single-photon loss. We pedagogically present the corresponding slow/fast perturbative argument (Section IV.B) as the translation to quantum notation of the standard dynamical systems approach, recalled in Section IV.A. Finally, simulations illustrate the validity of our analysis in Section V.

2 Driven dissipative pairwise photon process

The underlying space of the quantum harmonic oscillator is a Hilbert space \( \mathcal{H} \) of infinite dimension spanned by the Fock states \( \{|n\rangle\}_{n \in \mathbb{N}} \). The annihilation operator \( a \) is defined by \( a|n\rangle = \sqrt{n}|n-1\rangle \) for any \( n \geq 1 \) and \( a|0\rangle = 0 \). Its Hermitian conjugate \( a^\dagger \), verifies \( a^\dagger|n\rangle = \sqrt{n+1}|n+1\rangle \), for any \( n \geq 0 \). We denote \( N = a^\dagger a \) the photon number operator, satisfying \( N|n\rangle = n|n\rangle \), for any \( n \geq 0 \). For any \( \alpha \in \mathbb{C} \), a coherent state \( |\alpha\rangle \in \mathcal{H} \) is characterized by \( a|\alpha\rangle = a^\dagger|\alpha\rangle = \alpha|\alpha\rangle \) and

\[
|\alpha\rangle = e^{-\frac{\alpha^2}{2}} \sum_{n=0}^{\infty} \frac{\alpha^n}{\sqrt{n!}} |n\rangle.
\]

The coherent states \( |\alpha\rangle \) are viewed as the quantum model for a “classical state” of complex amplitude \( \alpha \). Indeed, whereas the classical undamped harmonic oscillator \( \frac{d}{dt} x = -\omega p \), \( \frac{d}{dt} p = \omega x \) with \( x, p \in \mathbb{R} \) has solutions \( x(t) = \alpha e^{i\omega t} \), the quantum harmonic oscillator \( \frac{d}{dt} |\psi\rangle = -i\omega(N + 1/2)|\psi\rangle \) features solutions \( |\psi(t)\rangle = |\alpha(t)\rangle = \alpha(t) |\alpha(t)\rangle \).
$|a e^{i\omega t}\rangle$ up to an irrelevant phase. As is customary, in the rest of the paper we describe the system in a frame rotating at the oscillator frequency $\omega$, for which the oscillator has stationary solutions $|\alpha\rangle$.

We call Schrödinger cat state or simply cat state the coherent superposition of two coherent states with opposite amplitudes,

$$|c^{\pm}_\alpha\rangle = \frac{|\alpha\rangle \pm |\alpha\rangle}{\gamma^\pm}$$

where $\gamma^\pm = \sqrt{2(1 \pm e^{-2|\alpha|^2})}$ is a normalization factor. If $|\alpha| \gg 1$ then we have $\gamma^+ \approx \gamma^- \approx \sqrt{2}$.

Throughout this paper, we denote by $K_1(H)$ the set of trace-class operators on $H$, i.e. compact Hermitian operators on $H$ whose eigenvalues $(\sigma_k)_{k\in \mathbb{N}}$ satisfy $\sum_{k\in \mathbb{N}} |\sigma_k| < +\infty$. This $K_1(H)$ equipped with the trace-norm $\text{Tr}(\cdot)$ is a Banach space (see e.g. [12]). The set of density operators (quantum states) corresponds to elements of $K_1(H)$ that are non-negative and of trace 1. They are usually denoted by $\rho$. We denote also by $K_f(H)$, the subspace of $K_1(H)$ of operators whose range is included in a vector space spanned by a finite number of Fock states:

$$K_f(H) = \left\{ \sum_{\text{finite}} f_{n,n'} |n\rangle \langle n'| : f_{n,n'} \in \mathbb{C}, f_{n,n'} = f^*_{n',n} \right\}.$$

We consider the quantum harmonic oscillator interacting with its environment as described in [8]. An external coherent driving field of amplitude $u$ (assumed here real and strictly positive without loss of generality) is applied such that the oscillator can only exchange photons in pairs. Furthermore, the quantum system is built such that similarly the main dissipative process is a pairwise photon loss with rate $\kappa > 0$. Nevertheless, due to physical constraints, even if a single photon loss process is much less frequent than the previous one, it can’t be totally omitted. For this reason, this term appears with a small coefficient $0 < \epsilon \ll \kappa$ in the following Lindblad master equation which governs the system dynamics:

$$\frac{d}{dt} \rho = u[(a^\dagger)^2 - a^2, \rho] + \kappa \mathcal{L}_{a^2}(\rho) + \epsilon \mathcal{L}_a(\rho)$$

where $[\cdot, \cdot]$ stands for the commutator and where, for any linear operator $A$ on $H$, the super-operator $\mathcal{L}_A$ is given by

$$\mathcal{L}_A(\rho) = A\rho A^\dagger - (A^\dagger A\rho + \rho A^\dagger A)/2.$$

Noting $\alpha = 2u/\kappa$ and $L = a^2 - \alpha^2$ one can reformulate the previous equation as :

$$\frac{d}{dt} \rho = \kappa \mathcal{L}_L(\rho) + \epsilon \mathcal{L}_a(\rho)$$

It is shown in [8] that, for $\epsilon = 0$, the two-dimensional Hilbert space

$$\mathcal{H}_\alpha = \text{span}\{|\alpha\rangle, |\alpha\rangle\}$$
is a decoherence-free space: for \( \epsilon = 0 \), any density operator \( \tilde{\rho} \) with support included in \( \mathcal{H}_a \) is a steady state, i.e., \( \mathcal{V}_L(\tilde{\rho}) = 0 \).

We will not investigate here the well-posedness of (2) and the associated strongly continuous semigroup of linear contraction on \( \mathcal{K}^1(\mathcal{H}) \). Such issues can be investigated via theorem 3.1 of [3] ensuring the existence of minimal solutions since for any \( \alpha, \kappa, \epsilon > 0 \), the operator \(-\kappa L^\dagger L - \epsilon a^\dagger a\) is the infinitesimal generator of a strongly continuous one parameter contraction semigroup on \( \mathcal{H} \). This means that, in the sequel, we will always assume that the Cauchy problem (2) with an initial condition \( \rho_0 \in \mathcal{K}^1(\mathcal{H}) \), positive semidefinite and of trace one, admits a solution in \( \mathcal{K}^1(\mathcal{H}) \) defined for any \( t > 0 \). Moreover, this minimal solution will remain positive semidefinite. We will investigate here the time asymptotic regime for \( \epsilon = 0 \) and then for \( 0 < \epsilon \ll \kappa \).

### 3 Convergence of (2) for \( \epsilon = 0 \)

**Lemma 1.** For any quantum state \( \rho \) in \( \mathcal{K}^1(\mathcal{H}) \) we have \( \text{Tr}(L\mathcal{V}_L(\rho)\rho^\dagger) \leq -2\text{Tr}(L\rho L^\dagger) \).

**Proof.** From \( \text{Tr}(L\mathcal{V}_L(\rho)\rho^\dagger) = \text{Tr}(L\rho L^\dagger[L^\dagger, L]) \) and \([L^\dagger, L] = [(a^\dagger)^2, a^2] = -4N - 2I\), we have

\[
\text{Tr}(L\mathcal{V}_L(\rho)\rho^\dagger) = -2\text{Tr}(L\rho L^\dagger(2N + I))
\]

We conclude since \( N \) and \( L\rho L^\dagger \) are positive semidefinite. \( \square \)

Modulo arguments proper to the infinite-dimensional setting, this basically means that \( V(\rho) = \text{Tr}(L\rho L^\dagger) \) is an exponential Lyapunov function for the system (2) with \( \epsilon = 0 \).

**Lemma 2.** For any \( \nu \geq 1 \) there exists \( \mu \geq 0 \) such that, for any quantum state \( \rho \) in \( \mathcal{K}^1(\mathcal{H}) \) we have

\[
\text{Tr}(\mathcal{V}_L^\dagger(\rho)N^\nu) \leq -\nu\text{Tr}(\rho N^\nu)^{\nu-1} + \mu
\]

**Proof.** Denote by \( \mathcal{V}_L^\dagger \) the adjoint of \( \mathcal{V}_L \): \( \mathcal{V}_L^\dagger(A) = L^\dagger AL - (L^\dagger LA + AL^\dagger L)/2 \) for any Hermitian operator \( A \) on \( \mathcal{H} \). Computations relying on the identity \( af(N) = f(N + I)a \) for any function \( f \), yield

\[
\mathcal{V}_L^\dagger(f(N)) = -N(N - 1)(f(N) - f(N - 2I))
+ \frac{\nu^2}{2} a^2(f(N) - f(N - 2I)) + \frac{\nu^2}{2}(f(N) - f(N - 2I))(a^\dagger)^2.
\]

Since \( \text{Tr}(\mathcal{V}_L(\rho)f(N)) = \text{Tr}(\rho\mathcal{V}_L^\dagger(f(N))) \), we have

\[
\text{Tr}(\mathcal{V}_L(\rho)f(N)) = -\text{Tr}(\rho N(N - 1)(f(N) - f(N - 2I)))
+ \frac{\nu^2}{2} \text{Tr}(\rho a^2(f(N) - f(N - 2I)))
+ \frac{\nu^2}{2} \text{Tr}(\rho(f(N) - f(N - 2I))(a^\dagger)^2).
\]
Take \( f(x) = x^\nu \) and define \( g(x) = f(x) - f(x-2) \) for \( x \geq 2 \); \( g(x) = f(x) \) for \( 2 > x \geq 0 \); \( g(x) = f(0) \) for \( x < 0 \). From \( a^2 g(N) = a \sqrt{g(N) - I} a \sqrt{g(N)} \) and Cauchy Schwartz inequality

\[
|\text{Tr}(\rho a^2 g(N))| = |\text{Tr}(\left( \sqrt{\rho} a \sqrt{g(N) - I} \right) (a \sqrt{g(N)} \sqrt{\rho}))| \\
\leq \sqrt{\text{Tr}(\rho g(N) - 2I)(N + I)} \text{Tr}(\rho g(N)N).
\]

Since \( g(x - 2)(x + 1) \leq g(x)(x + 3) \) for \( x \geq 0 \), we have

\[
|\text{Tr}(\rho a^2 g(N))| \leq \text{Tr}(\rho g(N)(N + 3I)).
\]

Thus

\[
\frac{1}{2} \text{Tr}(\rho(a^2 g(N) + g(N)(a^2)^2)) \leq \text{Tr}(\rho g(N)(N + 3I))
\]

and

\[
\text{Tr}(\Omega_L(\rho) N^\nu) \leq \text{Tr}(\rho g(N) (-N^2 + (\alpha^2 + 1)N + 3\alpha^2)).
\]

Since \((x^\nu - (x - 2)^\nu)(-x^2 + (\alpha^2 + 1)x + 3\alpha^2)\) is equivalent to \(-2\nu x^{\nu+1}\) for large \( x \), there exists \( \mu > 0 \) such that for all \( x \geq 0 \),

\[
((x + 2)^\nu - x^\nu)(-x^2 + (\alpha^2 + 1)x + 3\alpha^2) \leq -\nu x^{\nu+1} + \mu.
\]

Finally we get

\[
\text{Tr}(\Omega_L(\rho) N^\nu) \leq -\nu \text{Tr}(\rho N^{\nu+1}) + \mu
\]

Since \( x^{\nu+1} \) is concave, \( \left(\text{Tr}(\rho N^{\nu+1})\right)^{\frac{1}{\nu+1}} \geq \text{Tr}(\rho N^\nu). \)

\(\square\)

**Theorem 1.** Consider a trajectory \([0, +\infty[ \ni t \mapsto \rho(t) \in \mathcal{K}^1(\mathcal{H})\) of the master equation (2) with \( \epsilon = 0 \), \( \kappa > 0 \) and \( \alpha > 0 \). The following statements hold true:

1. Take \( \nu \geq 1 \). Then there exists \( \gamma > 0 \) such that, for any initial quantum state \( \rho(0) = \rho_0 \) satisfying \( \text{Tr}(\rho_0 N^\nu) < +\infty \), we have for all \( t > 0 \), \( \text{Tr}(\rho(t) N^\nu) \leq \max(\gamma, \text{Tr}(\rho_0 N^\nu)) \).

2. Assume that \( \rho_0 \in \mathcal{K}^1(\mathcal{H}) \). Then, there exists a quantum state \( \bar{\rho} \) with support in \( \mathcal{H}_a \) such that, for any \( \nu \geq 0 \), \( \lim_{t \to +\infty} \text{Tr}\left(\left|N^{\nu+1}(\rho(t) - \bar{\rho})N^{\nu+1}\right|\right) = 0 \).

The limit \( \bar{\rho} \) depends on \( \rho_0 \). It can be derived from \( \rho_0 \) with the four Hermitean, bounded and independent operators that are in the kernel of the adjoint superoperator \( \Omega_L^* \) and given in [8].
Proof. The first statement is a direct consequence of Lemma 2 and of the fact that quantum states element of $\mathcal{K}(\mathcal{H})$ are a dense subset of the quantum states $\sigma$ of $\mathcal{K}(\mathcal{H})$ with $\text{Tr}(\sigma N^v)$ finite. $\text{Tr}(\rho(t)N^v)$ remains bounded since
\[
\frac{d}{dt}\text{Tr}(\rho N^v) = \kappa \text{Tr}(\mathcal{L}_L(\rho)N^v) \leq -\nu \text{Tr}(\rho N^v)^{\frac{1}{2}} + \kappa \mu.
\]
Thus for $\text{Tr}(\rho N^v) \geq \lambda = \left(\frac{\kappa}{\nu}\right)^{\frac{1}{2}}, \frac{d}{dt}\text{Tr}(\rho N^v) \leq 0$.

The second statement exploits the first one. We can assume $v > 0$. Take $v' > v$.

Denote by $\mathcal{K}_{\nu}^1(\mathcal{H})$ the subspace of trace-class operators $\sigma$ such that $\text{Tr}\left(\left|\mathcal{L}_L(\sigma)N^v - \mathcal{L}_L(\sigma)N^{v'}\right|\right)$ is a Banach space. From the first statement, we know that $\rho_0$ being an element of $\mathcal{K}_{\nu}^1(\mathcal{H})$, $\rho(t)$ remains always in $\mathcal{K}_{\nu}^1(\mathcal{H})$. Since $v' > v$, the injection of $\mathcal{K}_{\nu}^1(\mathcal{H})$ into $\mathcal{K}_{\nu}^1(\mathcal{H})$ is compact: $\{\rho(t) | t \geq 0\}$ is precompact in $\mathcal{K}_{\nu}^1(\mathcal{H})$. Denote by $\bar{\rho} \in \mathcal{K}_{\nu}^1(\mathcal{H})$ an adherent point of $\rho(t)$ for $t$ tending towards infinity. Since $v \geq 2$, $\bar{\rho}$ and $\rho$ belong to the domain of $\mathcal{L}_L$. Lemma 1 implies $\text{Tr}(\mathcal{L}_L \bar{\rho}) = 0$, i.e., the support of $\bar{\rho}$ is contained in the kernel of $L$, which coincides with $\mathcal{H}_d$. Moreover, the semigroup associated to the Lindblad master equation is a contraction for the trace distance: for two trajectories $\rho_1(t)$ and $\rho_2(t)$, $t \mapsto \text{Tr}(\rho_1(t) - \rho_2(t))$ is a non-increasing function. Thus $t \mapsto \text{Tr}(\rho(t) - \bar{\rho})$ is non-increasing since $\bar{\rho}$ is a steady state. Consequently the adherent point $\bar{\rho}$ is unique: $\rho(t)$ converges towards $\bar{\rho}$ in $\mathcal{K}_{\nu}^1(\mathcal{H})$.

\[\square\]

4 Reduced slow dynamics of (2)

We have proved in the previous section that the system converges toward the decoherence free subspace $\mathcal{H}_d$ when we neglect the photon loss channel ($\epsilon = 0$). When $0 < \epsilon < 1$, the center manifold theorem allows us to separate the system into fast and slow dynamics. The fast dynamics makes the system globally converge to a subspace close to $\mathcal{H}_d$. The slow dynamics approximate the behavior of “protected states” $|\alpha_0^+\rangle, |\alpha_0^-\rangle$. The present section is aimed at characterizing these dynamics to the first order in $\epsilon$.

The fast/slow dynamics reduction from nonlinear systems theory, also known as singular perturbation theory, is useful despite the linearity of Lindbladian dynamics, because the very high dimension and often high degeneracy of open quantum systems makes matrix diagonalization impractical to apply.

For the sake of clarity, we first particularize the fast/slow dynamics reduction theory to linear systems of finite dimension with the standard notations. We propose then a reduction procedure via an adapted duality viewpoint with the characterization based on (9) and (10) here below. We apply then this characterization to the quantum system (2) and show that it facilitates the computations up to first order with respect to e.g. [6].
4.1 Reducing a linear system to its slow dynamics

We here review the theory of geometric singular perturbation, which was mainly developed by Fenichel in [4] and surveyed by Jones in [5], in a linear context. Consider the nominal linear system \( \frac{d}{dt}x = Ax \) with \( x = (x_1, x_2) \in \mathbb{R}^m \times \mathbb{R}^n \) and converging globally to the \( m \)-dimensional subspace \( S = \{ x \in \mathbb{R}^{m+n} : x_2 \in \mathbb{R}^n = 0 \} \). To this nominal dynamics we add an arbitrary perturbation matrix \( B \) of order \( \epsilon \ll 1 \).

In matrix notation, the dynamics can be written in block form which yields:

\[
\begin{align*}
\frac{d}{dt} x_1 &= A_1 x_2 + \epsilon (B_1 x_2 + B_0 x_1) \quad (3) \\
\frac{d}{dt} x_2 &= A_2 x_2 + \epsilon (B_2 x_2 + B_3 x_1)
\end{align*}
\]

The assumption that \( S \) is globally exponentially stable for \( \epsilon = 0 \) corresponds to \( A_2 \) having all eigenvalues with strictly negative real parts, thus it is invertible. Hence we can define the regular change of variables

\[
\begin{align*}
\tilde{x}_1 &= x_1 - A_1 A_2^{-1} x_2 \\
\tilde{x}_2 &= x_2
\end{align*}
\]

which yields dynamics in Tikhonov normal form

\[
\begin{align*}
\frac{d}{dt} \tilde{x}_1 &= \epsilon \left( (B_0 - A_1 A_2^{-1} B_3) \tilde{x}_1 \right. \\
&\quad + (B_0 + B_1 - A_1 A_2^{-1} (B_2 + B_3)) \tilde{x}_2 \\
&= \epsilon f(\tilde{x}_1, \tilde{x}_2) \\
\frac{d}{dt} \tilde{x}_2 &= A_2 \tilde{x}_2 + \epsilon (B_3 \tilde{x}_1 + (B_2 + B_3 A_1 A_2^{-1}) \tilde{x}_2) \\
&= g(\tilde{x}_1, \tilde{x}_2, \epsilon)
\end{align*}
\]

The Tikhonov conditions for reducing the system by singular perturbations is that the first (slow) subsystem has eigenvalues going down as \( \epsilon \), while the second (fast) subsystem has eigenvalues bounded away from zero for \( \epsilon = 0 \). These conditions are satisfied above. The Tikhonov theorem then allows the following reduction.

**Proposition 1**. The trajectories of the full system \((5),(6)\) (with initial conditions satisfying \( g = 0 \)) remain \( \epsilon \)-close over at least a time of order \( 1/\epsilon \), to the trajectories of the system restricted to the "slow submanifold" \( g(\tilde{x}_1, \tilde{x}_2, 0) = 0 \) and where dynamics are given by replacing \( \tilde{x}_2 \) in \( f(\tilde{x}_1, \tilde{x}_2) \) by the solution of \( g(\tilde{x}_1, \tilde{x}_2, 0) = 0 \).

In our linear case, the slow manifold comes down to \( \tilde{x}_2 = 0 \) and the slow dynamics trivially reduce to the first term in \((5)\). Transforming back to the original coordinates the slow manifold corresponds just to \( x_2 = 0 \) and the dynamics are

\[
\frac{d}{dt} x_1 = \epsilon (B_0 - A_1 A_2^{-1} B_3) x_1 .
\]

The second term reflects the influence of the fast \( x_2 \) dynamics on the slow variable \( x_1 \): by blindly setting \( x_2 = 0 \) in the original system \((3)\) and neglecting its second
Computing the corrective term $A_1A_2^{-1}B_3$ by explicit inversion of $A_2$ can be a tedious task when the fast subsystem has a large dimension (in our quantum case, $x_2$ would rigorously be of infinite dimension). However if first integrals of the system with $\epsilon = 0$ are known, these can facilitate the computations via the following dual viewpoint.

Consider a linear functional $p^T = (p_1^T, p_2^T) \in \mathbb{R}^{m+n}$ which is conserved by $\dot{x} = Ax$, i.e. satisfying $\dot{p} = A^Tp = 0$ or equivalently $p_1^TA_1x_2 + p_2^TA_2x_2 = 0$ for all $x_2 \in \mathbb{R}^n$. (The notation $^T$ denotes matrix transpose.) Again using invertibility of $A_2$, we see that $p^T$ actually satisfies

$$p_1^TA_1A_2^{-1}y + p_2^Ty = 0 \forall y \in \mathbb{R}^n. \quad (8)$$

Knowing $m$ linearly independent functionals $(p^T(k))_{k=1,...,m}$ satisfying (8) is sufficient to fully characterize the corrective term in (7): we have

$$\frac{d}{dt}x_1 = \epsilon(B_0 + Q)x_1 \quad (9)$$

with $Q$ defined by the set of linear equations:

$$p_1^T(k)Q = p_2^T(k)B_3, \quad k = 1, 2, ..., m. \quad (10)$$

### 4.2 Quantum system (2) with $0 < \epsilon \ll \kappa$

We now apply the same procedure to our quantum system. The nominal $\dot{x} = Ax$ corresponds to $\dot{\rho} = \mathcal{L}_L(\rho)$. We have shown in Section 3 that:

- $S$ corresponds to a four-dimensional real subspace of Hermitian operators spanned by $|c_\alpha^+\rangle\langle c_\alpha^+|$, $|c_\alpha^-\rangle\langle c_\alpha^-|$, $|c_\alpha^+\rangle\langle c_\alpha^-| + |c_\alpha^-\rangle\langle c_\alpha^+|$, and $i(|c_\alpha^+\rangle\langle c_\alpha^-| - |c_\alpha^-\rangle\langle c_\alpha^+|)$. These correspond to the $m = 4$ coordinates of $x_1$.

- The subspace $S$ is globally asymptotically stable under $\dot{\rho} = \mathcal{L}_L(\rho)$. This corresponds to the invertibility condition on $A_2$ independently of $\epsilon$.

We therefore introduce the projector

$$P_c = |c_\alpha^+\rangle\langle c_\alpha^+| + |c_\alpha^-\rangle\langle c_\alpha^-| \quad (11)$$

such that

$$\rho_s = P_c \rho P_c \quad (12)$$

corresponds to the “slow” $x_1$ space of the previous section. The projection onto “$x_2$ space” is given by

$$\rho_f = \rho - P_c \rho P_c.$$ 

Our goal is to compute the evolution of $\rho_s$, which is the equivalent of (7). For this we take advantage of the dual formulation (9),(10). The following procedure
Lemma 3. Specific to the structure of quantum Lindblad dynamics. We will also use the following key property of the conserved quantities, which is proved in the appendix of [8].

\[ P_c \mathcal{L}_a(\rho_s)P_c = \alpha^2 \mathcal{L}_X(\rho_s) \]

where \( X = \frac{\gamma_+}{\gamma_-} |e^+\rangle\langle e^-| + \frac{\gamma_-}{\gamma_+} |e^-\rangle\langle e^+|. \)

To compute the corrective term by duality, using the equivalent of (9),(10), we need to identify \( m = 4 \) conserved functionals of the system, which are the fixed points of the dual nominal dynamics \( \frac{d}{dt} \xi = \mathcal{L}_L^*(\xi) \). Fortunately, those invariants are known for the particular operator \( L \):

- One easily checks that \( \xi^a = I \) the identity operator is in the kernel of any \( \mathcal{L}_L^* \).
- The parity operator \( \xi^b = (-1)^{a^a} \) is in the kernel of \( \mathcal{L}_L^* \) because photons are exchanged by pairs.
- The appendix of [8] gives two more operators \( \xi^c \) and \( \xi^d \) in terms of Bessel functions; one checks that they are linearly independent for finite \( a \).

We will also use the following key property of the conserved quantities, which is specific to the structure of quantum Lindblad dynamics.

**Lemma 3.** Any Hermitian operator \( \xi \) in \( \ker(\mathcal{L}_L^*) \) commutes with \( P_c \) the orthogonal projector onto \( \mathcal{H}_a \).

**Proof.** From \( 2L^\dagger L = L^\dagger_1 L + \xi L^\dagger L \) and \( LP_c = 0 = P_c L^\dagger \) we have \( L^\dagger L \xi P_c = 0 = P_c \xi L^\dagger L \). Thus the Hermitian operator \( A = P_c \xi + \xi P_c \) satisfies \( LAL^\dagger = (L^\dagger _1 LA + AL^\dagger _1 L)/2 \), i.e. belongs to the kernel of \( \mathcal{L}_L \). The support of \( A \) is thus included in \( \mathcal{H}_a \) and thus \( [P_c, A] = 0 \). This implies that \( P_c \xi = P_c \xi P_c = \xi P_c \).

Considering projections on respective subspaces, the equivalent of the \( B_3 \) term of the linear perturbation is given by \( \mathcal{L}_a(\rho_s) = P_c \mathcal{L}_a(\rho_s)P_c \). The equivalent of equation (10) characterizes the Hermitian operator \( Q \) with support on \( \mathcal{H}_a \), as follows:

\[
\text{Tr} (P_c \xi^\nu P_c Q) = \text{Tr} \left( (\xi^\nu - P_c \xi^\nu P_c) (\mathcal{L}_a(\rho_s) - P_c \mathcal{L}_a(\rho_s)P_c) \right) \\
= \text{Tr} \left( \xi^\nu (\mathcal{L}_a(\rho_s) - P_c \mathcal{L}_a(\rho_s)P_c) \right) \\
= \frac{1}{2} \text{Tr} \left( \xi^\nu \left( (P_c - I)a^\dagger ap_a + \rho_a a^\dagger a(P_c - I) \right) \right) \\
= \frac{1}{2} \text{Tr} \left( \xi^\nu \left( a^\dagger ap_a(P_c - I) + (P_c - I)\rho_a a^\dagger a \right) \right) = 0
\]

for any \( \nu = a, b, c, d \). From the first to the second line, \( P_c \xi^\nu P_c \) is readily dropped since \( P_c \) is a projector. For the next one we have to write out \( \mathcal{L}_a \) and see that...
\[ P_a \rho_a a^\dagger P_c = a \rho_a a^\dagger \] for the particular perturbation operator \( a \). The last line follows by using Lemma 3 and \( P_a \rho_a = \rho_a \). As a conclusion, we get that the corrective term is \( Q = 0 \) for our particular case. We can summarize these computations as follows.

The trajectories of system (2) with initial conditions having supports in \( \mathcal{H}_\alpha \) remain \( \epsilon \)-close over at least a time of order \( 1/\epsilon \), to the trajectories of the “slow variable” \( \rho_s \) which is a linear combination of \( |e_\alpha^+\rangle\langle e_\alpha|, |e_\alpha^-\rangle\langle e_\alpha|, |e_\alpha^+\rangle\langle e_\alpha^-|, \rangle\langle e_\alpha^+| \), and \( \text{ii}(|e_\alpha^+\rangle\langle e_\alpha^-| - |e_\alpha^-\rangle\langle e_\alpha^+|) \). The slow state \( \rho_s \) follows the Lindblad dynamics:

\[
\frac{d}{dt} \rho_s = \epsilon a^2 \gamma X (\rho_s) \tag{15}
\]

where \( X = \frac{\gamma_+}{\gamma_-} |c^+\rangle\langle c^-| + \frac{\gamma_-}{\gamma_+} |c^-\rangle\langle c^+| \). \tag{16}

In applications considering \( |e_\alpha^+\rangle \) and \( |e_\alpha^-\rangle \) as canonical states \( |0\rangle, |1\rangle \) of a logical qubit [8], the operator \( X \) corresponds to a bit-flip in the limit \( \frac{\gamma_+}{\gamma_-} \rightarrow 1 \) of large coherent amplitude \( \alpha \) and to a decoherence to the vacuum \( |0\rangle \) in the limit of Fock states \( |e_\alpha^+\rangle = |n = 0\rangle, |e_\alpha^-\rangle = |n = 1\rangle \) when \( \alpha = 0 \). For all other cases, the qubit dynamics (15),(16) corresponds on the canonical Bloch sphere to:

\[
\frac{d}{dt} x = -\epsilon a^2 \left( \frac{\gamma_+^2 - \gamma_-^2}{2 \gamma_+ \gamma_-} \right) x
\]

\[
\frac{d}{dt} y = -\epsilon a^2 \left( \frac{\gamma_+^2 + \gamma_-^2}{2 \gamma_+ \gamma_-} \right) y
\]

\[
\frac{d}{dt} z = -\epsilon a^2 \left( \frac{\gamma_+^4 + \gamma_-^4}{\gamma_+^2 \gamma_-^2} \right) \left( z - \frac{\gamma_+^2 - \gamma_-^2}{\gamma_+^2 + \gamma_-^2} \right).
\]

This converges to \( x = 0 \) (slowly for \( \frac{\gamma_+}{\gamma_-} \approx 1 \), \( y = 0 \), and \( z = \frac{\gamma_+^2 - \gamma_-^2}{\gamma_+^2 + \gamma_-^2} \) (which is \( \approx 0 \) for \( \frac{\gamma_+}{\gamma_-} \approx 1 \)).

5 Numerical simulations

To illustrate the interest of this model reduction based on adiabatic elimination of the rapidly converging variables, we compare via numerical simulations trajectories of the complete system and of the reduced one. To do so, we use a numerical scheme which preserves the positiveness for the Lindblad equation and similar to one used in [7]. We choose the following values of the parameters: a time-step of \( 10^{-3} \), the decoherence strength \( \kappa = 1, u = 1/2 \) and \( \epsilon = 0.01 \). With \( \alpha = 1 \), the population of photons for \( n > n_{\text{max}} = 40 \) in the coherent state \( |\alpha\rangle \) is almost zero since less than \( \frac{1}{n_{\text{max}}} \). Consequently, we truncate the infinite-dimensional Hilbert space to a numerical system space spanned by \( \{|1\rangle,|2\rangle,\ldots,|40\rangle\} \) in the Fock basis. We denote by \( \rho \) the density matrix of the resulting system. It is worth stressing that the complete system is represented by an \( n_{\text{max}} \times n_{\text{max}} \) matrix while the reduced system...
is represented by a $2 \times 2$ matrix (on the basis $|c_+^\alpha\rangle, |c_-^\alpha\rangle$). Thus the computation is much faster on the second one.

We first take as initial condition the vacuum state, $\rho_0 = |0\rangle\langle 0|$. The state of the reduced system, $\rho_s$ is then initialized at $|c_+^\alpha\rangle\langle c_+^\alpha|$ because both $\rho_0$ and $|c_+^\alpha\rangle\langle c_+^\alpha|$ are $+1$ eigenstates of the parity operator $\xi^b = (-1)^{a^\dagger a}$, which is a conserved quantity (see Section 4.2 and [8]). To compare the trajectories of (2) initialized at $|0\rangle\langle 0|$ and of (15) initialized at $|c_+^\alpha\rangle\langle c_+^\alpha|$, we show in figure 1 the expectation values $\text{Tr}(\rho\sigma_z)$ and $\text{Tr}(\rho_s\sigma_z)$ of the operator $\sigma_z = |c_+^\alpha\rangle\langle c_+^\alpha| - |c_-^\alpha\rangle\langle c_-^\alpha|$, commonly denoted $\langle \sigma_z \rangle$.

After a transitional regime of typical duration $1/\kappa$, one can see a strong similarity between $\text{Tr}(\rho\sigma_z)$ and $\text{Tr}(\rho_s\sigma_z)$ up to a constant offset. The value of this offset is of order $\epsilon$. Furthermore, we plot the fidelity $F(\rho, \rho_s) = \text{tr}(\sqrt{\sqrt{\rho_s}\rho\sqrt{\rho_s}})$ between $\rho_s$ and $\rho$. For better readability, figure 2 shows the logarithm of 1 minus the fidelity, i.e. of its deviation from the ideal value 1. This deviation quickly converges to an order $10^{-4}$, corresponding to $\epsilon^2$ as expected. It then further decreases, incidentally, as both systems converge towards the unique equilibrium of the slow dynamics.

To emphasize the influence of $\gamma^+$ and $\gamma^-$ in (16), we add a simulation with the same parameters but with the following and same initial condition for the complete and reduced system:

$$\tilde{\rho}_0 = \frac{1}{2} \left( |c_+^\alpha\rangle + |c_-^\alpha\rangle \right) \left( \langle c_+^\alpha | + \langle c_-^\alpha | \right)$$

Figure 3 shows that the expectation value of $\sigma_x = |c_+^\alpha\rangle\langle c_-^\alpha| + |c_-^\alpha\rangle\langle c_+^\alpha|$ slowly decreases over time, as expected from bit-flip dynamics. The slope of this decrease is approximated to $\sim 4\%$ accuracy by the reduced dynamics. Moreover, figure 4 establishes that $\langle \sigma_z \rangle$ does not remain zero. This is due to the fact that, with $\gamma^+ > \gamma^-$, equation (15) “promotes” the population of $|c_+^\alpha\rangle\langle c_+^\alpha|$ over the population of $|c_-^\alpha\rangle\langle c_-^\alpha|$, unlike a pure bit-flip.

The simulations thus confirm the validity of our approximation of the complete model by the reduced one.

6 CONCLUSIONS

We have rigorously proved convergence of a harmonic oscillator Lindblad dynamics with two-photon exchanges, to a protected subspace. We have also established the approximate slow dynamics on this protected subspace when a typical perturbation is added, and illustrated its validity in simulations. The methods used for this particular example are applicable to general Lindbladian dynamics.

The reduction by singular perturbations and adiabatic elimination is of course applicable in general to evaluate the remaining slow dynamics in quantum systems with (engineered) protected subspaces. Extension to $k$-photon processes $a_k^\dagger$ with $k > 2$ can be addressed in the same way. The fact that the slow variable still follows a Lindbladian master equation may not be surprising but remains to be proved
Figure 1: Comparison of $\text{Tr}(\sigma_z \rho)$ and $\text{Tr}(\sigma_z \rho_s)$ for $\rho$ solution of the complete system (2) with $\epsilon = 1/100$, $\alpha = 1$ and vacuum initial condition (truncation up to 40 photons), and for $\rho_s$ solution of the reduced system (15) with initial condition $|c_{+\alpha}\rangle\langle c_{+\alpha}|$.

Figure 2: $\log_{10}(1 - F)$ where $F$ is the fidelity between $\rho_s$ and $\rho$ for the simulations of figure 1.
Figure 3: Comparison of $\text{Tr}(\sigma \rho)$ and $\text{Tr}(\sigma \rho_s)$ for $\rho$ solution of the complete system (2) with $\epsilon = \frac{1}{100}$, $\alpha = 1$ (truncation up to 40 photons), and for $\rho_s$ solution of the reduced system (15), with the same initial condition $\rho(0) = \rho_s(0) = \frac{1}{2} (|c_\alpha^+\rangle + |c_\alpha^-\rangle) \left(\langle c_\alpha^+| + \langle c_\alpha^-|\right)$.

Figure 4: Comparison of $\text{Tr}(\sigma \rho)$ and $\text{Tr}(\sigma \rho_s)$ where $\rho$ and $\rho_s$ correspond to simulations of figure 3.
in the general case. The fact that the dynamics reduces to the orthogonal projection of the Lindbladian onto the protected subspace (i.e. $B_0$ without any correction due to $B_3$, in the terms of Section 4.1) for the case examined here would be in agreement with the physicists’ “quantum Zeno” viewpoint. However, under which formulation this viewpoint should be applied in the general case also remains to be rigorously characterized.

ACKNOWLEDGMENT

The authors thank Mazyar Mirrahimi for many useful discussions.
